

AWS IAM User Creation, MFA Setup, and S3 Access Verification

Objective: To create a new IAM user, enable AWS Management Console access, configure multi-factor authentication (MFA), attach the AmazonS3FullAccess policy, and verify the user sign-in and permission scope.

IAM User Name: Sypher

Policy Used: AmazonS3FullAccess

Security Control: MFA enabled using an authenticator app

Step 1: Log In to the AWS Management Console

Open the AWS Management Console and sign in with the management account. After successful authentication, the Console Home page becomes available.

Step 2: Search for IAM and Open the Service

Use the global AWS search bar to find **IAM** and open the Identity and Access Management service. The IAM dashboard provides access to users, groups, roles, policies, and account security settings.

Step 3: Review the Existing Users List

Navigate to the **Users** section in IAM to review the current user accounts. This confirms the starting state before creating the new IAM user.

Step 4: Start Creating a New IAM User

Click **Create user** and enter the new user name **Sypher**. Enable access to the AWS Management Console and choose the option to create an IAM user for console sign-in.

Step 5: Review Permission Settings and Configure the User Creation Flow

Continue to the permissions step and review how permissions will be assigned. During the creation workflow, an S3-related managed policy boundary was selected before proceeding to the review stage.

Step 6: Create the User and Retrieve the Initial Password

Create the user and note the generated sign-in details page. This page confirms successful IAM user creation and provides the sign-in URL for console access.

Step 7: Verify That the New User Appears in IAM

Return to the users list and confirm that the newly created IAM user **Sypher** appears in the table.

Step 8: Open the User Summary and Review the Initial State

Open the user details page for **Sypher**. At this stage, console access is enabled, MFA is not yet configured, and no permissions policy is directly attached.

Step 9: Start MFA Configuration

Begin the MFA setup process for the IAM user and choose **Authenticator app** as the MFA device type. This improves security by requiring a second factor during sign-in.

Step 10: Complete MFA Enrollment

The authenticator application was linked successfully and MFA registration was completed. For security reasons, the QR-code enrollment screen is intentionally omitted from this report.

Step 11: Attach the AmazonS3FullAccess Policy

Next, use **Add permissions** and select **Attach policies directly**. Search for and choose the AWS managed policy **AmazonS3FullAccess**, then review and apply the policy to the user.

Step 12: Verify the User Summary After MFA and Policy Configuration

After the update, return to the user details page and confirm that **AmazonS3FullAccess** is attached directly to the user. The summary page also confirms that console access is now protected with MFA.

Step 13: Sign In as the IAM User

Open the IAM user sign-in URL, enter the account ID, IAM username, and password, and proceed with the sign-in process.

Step 14: Complete MFA Verification at Sign-In

During authentication, AWS prompts for the MFA code generated by the registered authenticator application. Entering the valid MFA code completes the secure sign-in process.

Step 15: Verify Console Access as the New IAM User

After sign-in, the AWS Console opens under the IAM user session. The account menu confirms that the active signed-in identity is **Sypher**.

Step 16: Validate Permission Scope by Opening EC2

Finally, open the EC2 dashboard while signed in as the IAM user. The resulting API and authorization errors indicate that the user has limited permissions and does not have full EC2 access, which aligns with the S3-focused policy assignment.

Result

The IAM user **Sypher** was created successfully, MFA was enabled, and the AWS managed policy **AmazonS3FullAccess** was attached directly to the user. The user was able to sign in to the AWS Console using MFA, and the final verification confirmed that access remained limited, demonstrating controlled permissions.
